FORECASTING ACADEMIC SUCCESS IN SPECIFIC COLLEGES

Donald P. Hoyt

American College Testing Program

Part I. The Problem

One of the most obvious trends in American education is the increasing proportion of youngsters seeking post high school education or training. The ratio of number of college students to the total number in the 18-21 age group has risen steadily from 14 out of 100 in 1939 to 46 out of 100 in 1965. It is expected to reach 55 out of 100 by 1974. Whereas there were about 1.3 million college students in 1939, there were 5.5 million in 1965 and about 8.7 million are expected in 1974 (Office of Education, 1965a, 1965b; Bureau of Census, 1964).

This trend is accompanied by an immense diversity in the needs and talents of college-bound youth. No longer is college a place exclusively for the leisure class, or for training ministers and doctors, or for the intellectual elite. It has become a major means of preparing students for a vast array of occupations. The demands of the vocational world for more and more people with specialized skills and understandings, together with the willingness of higher education to adapt its curricula to these demands, account in large part for the dramatic increase in the numbers of high school graduates seeking admission to college. It has also led to enormous differences among colleges in purposes, philosophies, facilities, students, and the many other ingredients of higher education.

A number of research studies have documented the diversity in higher education. For example, McConnell and Heist (1962) found that, in a representative sample of 200 colleges, the average score on the American Council on Education Psychological Examination ranged from 37.5 (below the first percentile for college freshmen nationally) to 142.2 (above the 90th percentile for all college freshmen). Similarly, in an 11 college study, Goldsen and her colleagues (1960) found that 80% of the students at Fisk felt that vocational training should be emphasized, while only 30% of Harvard freshmen endorsed this as a legitimate emphasis in college. And in other studies, wide differences have been found among colleges in the degree to which their freshmen aspired to advanced degrees, planned to work part-time, were influenced in their choice of college by economic factors, or had attained success in out-of-class activities in high school (Hoyt, 1968a, 1968b).

These institutional differences, while giving a chaotic picture of higher education in America, are generally viewed as desirable. They illustrate some of the major individual differences among high school seniors. Because a large proportion of this diverse group will enroll in "college," different kinds of colleges will be needed.

Whether by design or by chance, American society has produced an extremely wide range of opportunities for post-high school training. However, the problem of selecting a college which is well suited to the capacities and

needs of a given student has not been resolved. The secondary school counselor, because of his interest, experience, and training, is expected to play a key role in this decision by providing useful information to the student and by helping the student explore his capacities, interests, and values.

Pre-College Guidance -- A Model

A general model for providing assistance to individuals in making and implementing effective plans has been available since the time of Parsons and before (Zytowski, 1967). The model requires understanding the person, understanding the nature of the choices available to him, and combining these understandings to maximize the probability that the individual's goals can be realized.

Applied to the pre-college guidance setting, the model requires, first, that the student arrive at a realistic assessment of his characteristics as they relate to his needs for higher education. Whether or not a given characteristic is relevant to planning is often a matter for individual decision making. For example, two students may each correctly characterize themselves as highly social in orientation. One may believe that the satisfaction of his social drives is relatively unimportant at this time, and thus campus social opportunities are irrelevant to his choice of college; the other may believe that the opportunity to express his social nature and develop his social skills is highly important and will seek a college which facilitates the achievement

of these goals.

There is no definitive list of the personal characteristics which should be assessed. But it does seem desirable for all college-bound students to have a clear concept of their goals in attending college and an accurate understanding of their potential for reaching these goals.

The model requires that college opportunities be understood in a similar manner; that is, those aspects of the college which are relevant to the individual's goals and capacities should be known prior to the time that an application is made. For individual students, this may require knowledge of the extra-curricular opportunities, of the athletic program, of the library, of the national reputation of the faculty in a given department, or of many other environmental features which will facilitate or inhibit the student's ability to reach his goals. Almost all colleges set minimum standards of academic achievement which the student must reach if he is to re-enroll and eventually graduate. Therefore, for most students, an understanding of the academic characteristics of the college including the level of competition, the severity of grading practices, and the nature of academic probation and dismissal policies, is required.

Helping the student understand himself, the nature of the choices available to him, and the means by which these understandings can be integrated into a plan which promises to have satisfying outcomes are important responsibilities of the counselor.

Current Status

The effectiveness of the counselor in assisting his pre-college client depends upon the student's readiness to accept help, the counselor's professional skill, the counselor-client relationship, and the adequacy of the information which can be brought to bear on the situation. Our present understanding is inadequate to guarantee that optimal conditions will exist in any of these areas.

In the past few years, there has been considerable improvement in the quality and scope of information about colleges available to counselors. The publications of Astin (1965), Cass and Birnbaum (1965), Gleazer (1967), and Cartter (1964) are especially helpful because of their comprehensiveness and objectivity. But these publications have been unable to supply adequate information on one critical aspect of the college, namely its academic demands. It is this kind of information which the present monograph seeks to provide.

The Educational Need

Counselors and others concerned with "the great sorting" process of college admissions have long been aware of the need for information about the level of academic competition and the grading standards characteristic of a given college. Some progress has been made in obtaining such information for certain colleges. For example, the College Entrance Examination Board (CEEB, 1967) published academic information about 520 colleges that

volunteered to release it; academic aptitude distributions were usually included, and some colleges also provided their distribution of freshman grades. More complete academic information is available for the colleges in Utah (Jex, 1966), Minnesota (Johnson et. al., 1961), and Georgia (Hills et. al., 1965). Special manuals have been prepared for these states which provide specific equations for predicting academic success at each college. These predictions are based on the results of a standardized aptitude test and a summary of the high school record; since a separate equation is prepared for each college, differences in grading standards are taken in account as well as differences in the academic potentials of their students. Unfortunately, these guides include only a small portion of the colleges and universities in America.

Yet students, counselors, and parents need to know a student's likelihood for obtaining satisfactory grades at any college a student may wish to consider. If a student's academic achievement could be forecast for all colleges, the promotion of student potential and well being would be considerable. Such information would nurture not only our human capital but the resources of higher education, for student attrition within the college years is usually destructive for both students and colleges.

The alternatives to this point of view appear less tenable. If academic information is not available, students, counselors, and parents use unreliable substitutes: rumor, anecdotes based on one or two students, crude or incomplete information from the growing galaxy of commercial

guides, etc.

To secure more useful and comprehensive information, there are only two major alternatives: (1) persuade all colleges to provide the necessary information, or (2) use the current public information about colleges and universities to supplement college guides and other less reliable and incomplete reports about colleges.

This report considers how public information about colleges can be used to make predictions of academic accomplishment which will benefit students, counselors, parents, and colleges.

The Research Problem

The statistical ideal would be to develop an accurate equation for predicting grades at every college. A considerable literature exists on academic prediction studies (e. g. , Lavin, 1965). We know that the most useful predictions are made when both a scholastic aptitude test and the high school record are used. The literature also tells us that separate equations for boys and girls are desirable for the latter usually excel in both college grades and high school grades but not on scholastic aptitude tests. Furthermore, the academic achievement of girls can usually be predicted more accurately than can that of boys.

Previous research has not settled the question of whether unique regression weights need to be developed for every college. While, in practice, unique equations are usually developed for each college, there has been no careful study of how wide the differences are in the weights so

developed. An informal examination of several hundred such equations suggested that a fairly "standard" pattern of weights may exist. Empirically, research done on the Washington Pre-College Testing Program suggested that equations developed for the University of Washington could be usefully applied to other four-year colleges in that state (Lunneborg, 1966). From these considerations, it was hypothesized that one could find a single set of weights--one for the high school record and one for a scholastic aptitude score--that would "work" satisfactorily for almost any college.

In a preliminary study, this supposition was tested by developing a "general prediction equation" and comparing its predictive accuracy with that of unique equations developed at each of 23 individual colleges (Hoyt, 1963). The general equation correlated with grades nearly as well as did the unique equations. It appeared practical then, to use the same regression weights for every college.

The preliminary study also revealed the major weakness in generalized prediction. Despite generally satisfactory correlations, the accuracy of prediction at individual institutions was often unsatisfactory. In some colleges, predictions were frequently too high, and in others they were frequently too low. Such systematic errors do not affect the correlation coefficient, but they do reduce the usefulness of generalized equations.

Systematic errors in prediction occur because colleges differ in their

grading practices and in the level of academic potential which characterizes their freshman class. Furthermore, there is little relationship between the level of grades and the level of academic ability as measured by a standardized test.¹ Clearly, the practical usefulness of generalized equations depends upon our ability to take these differences into account.

The Procedure²

Guided by previous research, we decided to use two measures to predict grades--one reflecting the high school record and one reflecting performance on a standardized test of academic potential. Because of their accessibility, measures routinely reported by The American College Testing Program were chosen. These included high school average (HSA) and the ACT Composite (ACT-C).

HSA is the average of four self-reported high school grades. At the time that the student writes the ACT examination, he is asked to report his most recent term grades in English, mathematics, social studies, and natural sciences. Grades earned in the senior year are excluded so that

¹In a study of 79 junior colleges, mean GPA and mean ACT Composite correlated only .05 (Hoyt, 1968a) while in 169 four-year colleges this correlation was .33 (Hoyt, 1968b).

²The research summarized here is reported in more detail in an article which will appear in the Personnel and Guidance Journal (Hoyt, 1968c).

typically these grades reflect high school performance in the junior year. Because not all students register for courses in all four areas during their junior year, it is sometimes necessary to include courses taken in the sophomore or freshman years. Previous research has established that these grades are generally reported accurately; further, they have been shown to be as predictive of college grades as the more familiar high school rank (HSR) (American College Testing Program, 1965).

The ACT Composite is the average of the standard scores for the four tests of educational development included in the ACT Battery. These tests assess the student's ability to perform academic tasks typically required by college courses in English, mathematics, social studies, and natural sciences. The tests have been shown to be as predictive of college grades as other tests of academic potential (Munday, 1965; Buros, 1965).

An empirical approach was taken to the problem of the relative weight to give to HSA and ACT-C. Optimal weights were computed for each sex for a sample of 50 four-year colleges which had participated in one of the American College Testing Program's predictive services. Although the ratio of the ACT-C weight to the HSA weight ranged from 1:.7 to 1:3.2, most of the ratios were near the median of 1:1.2. This ratio held for both sexes and was used to develop the general prediction equations.

This same sample of 50 colleges was used to estimate certain other statistical constants needed to develop these questions. Thus, it was

discovered that the typical girl had an HSA which was .33 higher than the typical boy; similarly, the ACT-C for girls averaged .33 below that for boys, and girls typically had a college GPA which was .29 above that of the typical male. Median standard deviations on each of these measures were also computed for each sex. All of these data were used in a standard manner to develop prediction equations.

To deal with the problem of systematic errors in prediction, it is necessary to be able to estimate three constants for any college--the mean ACT-C, the mean HSA, and the mean college GPA. And, since not all colleges provide these data, these estimates must be made from published non-confidential sources of information. For this purpose, the "college profile" scores provided by Astin (1965) were used. Before describing how these scores were employed, it may be helpful to review their nature briefly.

A few years ago, Astin and Holland (1961) proposed a new and simple method for measuring the college environment. From Holland's theory of vocational choice (Holland, 1959), they reasoned that (a) the most important features of a campus environment were those created by its students, (b) the type of atmosphere created on a given campus would depend upon the proportions with which each of several types of students were represented, and (c) that the presence of important types of students could be inferred from knowledge of the number of students graduating each year in each of six

areas of study (Realistic, Intellectual, Social, Conventional, Enterprising, and Artistic). Since students and adults in these fields have been shown to have different patterns of abilities, interests, competencies, and personality traits (Holland, 1966), it is reasonable to suppose that a college dominated by one of them would provide an atmosphere distinct from that of a college dominated by another. The Astin-Holland Environmental Assessment Technique (EAT) simply described the percentage of graduates in each of these six fields, using data routinely supplied by the United States Office of Education. By simple statistical manipulation, these percentages were converted to standard scores with a mean of 50 and standard deviation of 10. Two other items were included in the EAT: the size of the student body (taken from an Office of Education publication), and the estimated "selectivity" of the institution. The latter was compiled on the basis of the relative popularity of colleges with students scoring high on the National Merit Scholarship tests; the more popular the college relative to its total size, the higher the selectivity score.

In other studies, Astin focused his research attention on the question, "What are the major dimensions of student characteristics which differentiate among institutions of higher education?" (Astin, 1964a). After collecting some 52 items of information descriptive of student characteristics at 248 diverse colleges, Astin was able to show that these described six basic dimensions upon which entering classes differed. These dimensions were labeled Intellectualism, Estheticism, Status, Pragmatism, Masculinity,

and Leadership.

In another study Astin (1962) showed that four factors--affluence, size, private control, and "masculinity"--accounted for most of the known differences among higher educational institutions. Using data from the United States Office of Education, the American Council on Education, the National Research Council, and the National Merit Scholarship Corporation, Astin correlated measures of these four factors, as well as EAT scores, with measures of the six dimensions of student characteristics discovered earlier (Astin, 1964b). In this important investigation, it was found that five of the six dimensions could be accurately predicted from the objective descriptions of the colleges. College characteristics correlated only .58 with the "Leadership" dimension, but for the other five student characteristics, correlations ranged from .73 to .90.

Since, with the exception of "Leadership," basic student characteristics could be inferred from measures of college characteristics, and since the latter were generally available in published sources, Astin was able to supply "college profiles" for over 1,000 accredited four-year colleges (Astin, 1965). These profiles included both the EAT and the student characteristics estimated from EAT scores and other objective indices of college characteristics.

Could Astin's "profile scores" be used to estimate the three means needed to "adjust" the generalized predictions and to take into account

differences in grading standards and the academic potential of entering students? This question was explored by using a sample of 169 four-year colleges which had participated in one of ACT's predictive research services in 1965 or 1966. The mean ACT-C, HSA, and first year college GPA were recorded for each college. Astin's 13 scores were then correlated with each of these measures. After eliminating any of Astin's scores which did not contribute significantly to the accuracy of prediction, multiple correlations of .78, .58, and .59 were obtained with mean ACT-C, mean HSA, and mean college GPA, respectively. To check the stability of the equations used in predicting these three means, a new sample of 207 colleges was drawn. Cross-validation coefficients of .78, .63, and .54 were obtained, suggesting that the original findings were reasonably stable.

While these correlations were encouraging, only the .78 associated with the ACT Composite could be considered high enough to justify estimates for individual colleges. Many sizeable errors would be made if mean HSA or mean college GPA on a given campus were estimated from Astin's scores.

It is possible that these errors might have a compensating effect upon each other. That is, if the estimated HSA at a given college was too low, the estimated college GPA might also be too low so that a prediction equation which relied on both estimates might yield satisfactory results despite these errors. The next phase of the study explored this question.

A new sample of 18 colleges was used, representing all regions of the

country and most of the types of four-year colleges. How accurately could the college grades of the student sample for one year be predicted from (a) the institution's own prediction equations developed from results for the previous year's freshman class, and (b) the generalized equation developed in this investigation?

As we noted earlier, accuracy is reflected both in the predictive correlation and in the magnitude of the difference between predicted and obtained. For the 18 colleges, the medians of the two sets of correlations (specific equation and general equation) were identical; the largest difference between the two was only .04. Further, the generalized equations (adjusted by the mean ACT-C, HSA, and college GPA estimated from Astin's scores) made no more systematic errors than did the unique institutional equations developed from the records of the previous year's freshmen.

Since the 18 colleges were chosen to reflect the diverse elements in higher education, and since the generalized method was eminently successful with them, there is reason to believe that the method could be effectively applied to any college for which Astin has published a profile. The necessary computational work has been done and the results appear in Part II of this report. The Appendix provides a detailed description of how these computations were made.

Part II. Application

The research reported in Part I established a method for predicting grades at any four-year college from a knowledge of the student's ACT Composite score and his recent high school grades in four areas. This section applies these results to nearly 1,000 four-year colleges.

Before examining the specific procedures, it may be helpful to look at two questions. (1) Suppose a given college has released predictive information to high school counselors which yields predictions that are inconsistent with those made through data supplied in this publication. Which should be used? If the college has released current prediction equations, these should be used rather than the results reported here. Although no evidence has been found that local equations are superior, it is unlikely that they would be inferior. (2) Can the findings be used for students who do not write the ACT Examination? In particular, since many colleges require the results of the Scholastic Aptitude Test (SAT) of the College Entrance Examination Board, could SAT scores be used in place of ACT scores? Several studies have shown that the ACT-Composite and the total SAT score (V + M) are highly correlated. As a result, tables of "equivalency" can be constructed. While there are many technical and practical reasons why the SAT and ACT tests could never be considered as identical measures, it is usually possible to infer a student's standing on one from his standing on the other. Chase and Barritt (1966) have recently published a table of concordance between ACT and SAT; an adaptation of this

table is shown in Figure 1.³ By using this table, SAT scores could be "converted" to ACT-C scores which could then be used for prediction purposes.

Figure 1

³Thanks are due to Clinton I. Chase, L. Spencer Barritt, and the

A note of caution is in order. The converting process (SAT to ACT) represents an additional manipulation of data, and the effect of this on predictive accuracy is unknown. Therefore, if complete information about a college's academic characteristics has been published in the Manual of Freshman Class Profiles (CEEB, 1967), it should be used in preference to the data in this publication.

To predict the academic success of a given student at specific four-year colleges requires the following procedures:

1. Record the student's ACT Composite score (or the ACT Composite score converted from the SAT V + M score) and his HSA. The HSA should be computed on a four-point scale (A=4; B=3; C=2; D=1; F=0). From the student's transcript, determine his most recent term grade, prior to the senior year, in English, mathematics, social studies, and natural science.

The chart below enumerates all possibilities:

<u>High School Grades</u>	<u>HSA</u>
AAAA	4.00
AAAB	3.75
AAAC; AABB	3.50
AAAD; AABC; ABBB	3.25
AAAF; AACC; AABD; ABBC; BBBB	3.00
AABF; AACD; ABBD; ABCC; BBBC	2.75

³(cont.) Journal of College Student Personnel, for their permission to reproduce the data shown in Figure 1.

<u>High School Grades</u>	<u>HSA</u>
AACF; AADD; ABBF; ABCD; ACCC; BBBD; BBCC	2.50
AADF; ABCF; ABDD; ACCD; BBBF; BBBD; BCCC	2.25
AAFF; ABDF; ACCF; ACDD; BBCF; BBDD; BCCD; CCCC	2.00
ABFF; ACDF; ADDD; BBDF; BCCF; BCDD; CCCD	1.75
ACFF; ADDF; BBFF; BDDD; BCDF; CCCF; CCDD	1.50
ADFF; BCFF; BDDF; CCDF; CDDD	1.25
AFFF; BDFF; CCFF; CDDF; DDDD	1.00
BFFF; CDFD; DDDF	0.75
CFFF; DDDF	0.50
DFFF	0.25
FFFF	0.00

2. Use Table A-1 (men) or Table A-2 (women) to develop a "general academic potential" index for the student. This is done by finding the column corresponding to the student's HSA, the row corresponding to his ACT Composite score, and the cell where this row and column intersect.

3. Convert this index into a predicted GPA by adding the college constant given in Table B. The obtained prediction is on a four-point scale where A=4, B=3, C=2, D=1, and F=0.

4. Use Table C to estimate the student's probability of earning a first-year GPA below C, between C and B, or B or higher.

Illustration: Mary Jones is considering two Iowa colleges: Iowa Wesleyan and Iowa State University. She has an ACT Composite standard score of 20. Her transcript shows that, prior to her senior year, her

most recent high school grades were B in English, C in mathematics, A in social studies, and C in natural science, giving her an HSA of 2.75 ($\frac{3 + 2 + 4 + 2}{4}$). Table A-2 shows that her "academic potential" index is 2.51. The regression constants for women at Iowa Wesleyan and at Iowa State University (Table B) are -.12 and -.49 respectively. Thus, her predicted GPA at Iowa Wesleyan is 2.39 (2.51-.12); at Iowa State University, her predicted GPA is 2.02 (2.51-.49). These figures can be rounded to 2.4 and 2.0; then Table C can be used. It shows that the probability of earning below a C average is estimated as 24/100 at Iowa Wesleyan and 50/100 at Iowa State University.

Table B also includes an estimate of the mean ACT Composite score at each college. This estimate is given as an interval, which reflects the predicted mean plus and minus one standard error of estimate. Thus, the chances are 2 out of 3 that the "true" mean for the institution lies within this range. For some colleges, the ACT Composite estimate may be more valuable than the predicted GPA. This will often be true of highly selective colleges that admit only a portion of the applicants capable of doing satisfactory academic work. Since these colleges must deny admission to many students with predicted GPAs of 2.0 or higher, the difference between the student's ACT Composite and the college's predicted ACT Composite mean may provide a more reliable indication of his academic acceptability than does his predicted GPA at that college.

Some Limitations

Before making practical applications of these data in pre-college guidance, counselors should be aware of the following limitations:

1. Only four-year accredited colleges for which Astin published profiles are included. Two-year colleges, unaccredited colleges, or recently accredited colleges have been omitted.

2. The possibility of change in entering classes at individual colleges should be recognized. Astin's evidence suggests that such change is rare. Nonetheless, counselors should be alert to changes in college policies which may affect the nature of the student body and therefore the current validity of previously developed regression equations.

3. Especially in complex institutions, a single prediction of academic success may be unsatisfactory since it ignores differences among curricula. Preliminary research shows that in complex colleges, freshmen in Education, Business Administration, or Engineering Sciences typically differ significantly from the freshman class as a whole. On the other hand, Liberal Arts freshmen usually resemble the entire freshman class in their academic characteristics. Modal differences between these curricular groups and the entire freshman class are shown in Figure 2. This figure shows that freshmen enrolling in the Education curriculum at a complex college or university typically average 1.3 standard score points on the ACT Composite below the average for the entire freshman class. These Education freshmen typically had slightly higher HSAs than did all freshmen

Figure 2

Typical Academic Differences Between All Freshmen and
Freshmen Enrolling in Selected Curricular Groups in
Complex Colleges and Universities

<u>Curriculum Group</u>	<u>Mean ACT Composite</u>	<u>Mean HSA</u>	<u>Mean College GPA</u>
Education	-1.3	+.05	+.05
Business Administration	-0.8	-.21	-.14
Engineering Science	+1.8	+.11	-.05
Liberal Arts	+0.7	-.03	-.02

and also earned slightly higher college GPAs. Students in Engineering Sciences typically were above the college's average on both the ACT Composite and HSA but were awarded grades which were slightly lower than those typically given at the college.

Further research must be done to establish the counseling implications of these findings. The evidence so far suggests that no correction should be made in academic predictions for students planning to enroll in Liberal Arts or Business Administration curricula; about .1 should be added to the GPA predictions for students planning to enroll in Education, and about .2 should be subtracted from the GPA predictions for students planning to enroll in an Engineering Science curriculum. It should be emphasized that new research may suggest revisions in these "correction" figures and may

identify other curricular groups for which corrections should be made.

4. While the evidence reported here suggests that generalized equations will probably predict as accurately as unique institutional equations, there is no dependable way of knowing the predictive efficacy of either type of equation at a given college. In general, the more an institution selects its students on the basis of their academic potentials, the lower the predictive correlation will be. For these colleges, the predicted mean ACT Composite will probably be more helpful to the counselor than the student's predicted GPA.

5. Because of statistical regression, the predicted ACT Composite means (Table B) probably contain systematic errors. In particular, predicted means in the range of 22-25 may be about one standard score too low, and those above 25 about two standard scores too low. Conversely, predicted means in the 16-19 range may be about one standard score too high, and those below 16 about two standard scores too high.

Counseling Uses

The tables in this publication are intended to provide the counselor and his pre-college client with some helpful information about the probable academic success of the latter, but they are not a substitute for more current, predictive information provided by individual colleges. It is important that both counselor and client put this information in proper perspective.

For many students, the information may be relatively irrelevant.

Effective counseling will usually establish what kinds of information the student needs. It is quite conceivable that the pivotal issues in the college choice process will revolve around questions unrelated to academic success. Cost, location, curricular offerings, special programs (independent study, remedial reading, junior-year abroad, etc.), prestige, student services, social climate, or a variety of other factors may be more germane to the student's choice of a satisfactory college. To routinely refer to the academic predictions made in this report, without regard to whether they represent information which the student desires or needs, would be poor counseling strategy.

Of course, counselors should be concerned that student choices reflect reality considerations. Students who make tentative college choices where they have low probabilities of succeeding, or low probabilities of being accepted, should be informed of these realities even if they fail to formulate questions which provoke this information. It is conceivable that the reasons for such choices are sufficiently compelling that the student will attempt to implement his plans despite the bleak prognosis, and counselors must be careful not to place negative value judgments on such decisions. But it also happens that students may overlook or be unaware of the differences in academic demands made by various colleges. Such students should not be denied this information simply because they failed, in their exploration of plans, to perceive its relevance to the decisions they face.

Similarly, academically able students who are considering colleges where the general level of academic competition is low should be encouraged to reflect upon the potential consequences of such a choice. For some, the possibility of boredom through lack of intellectual competition and stimulation may be seen as an important deterrent. Others may have psychological needs which require that they produce superior academic records, so that a sizeable difference between their academic potential and the college's academic demands would be perceived as a positive sign.

One further consideration should be added to the perspective provided by the preceding discussion. Counselors and their clients should be aware that academic success represents only one type of accomplishment. A number of studies have shown that distinguished performance outside of the classroom, whether in high school or in college, bears little relation to high school grades, college grades, or tests of academic potential (Holland & Richards, 1965; Richards, Holland & Lutz, 1967). Furthermore, the literature on the relationship of college grades to measures of adult success is consistent in showing that the two are either unrelated, or, at best, modestly correlated (Hoyt, 1966). In helping youngsters plan their future, counselors should be aware that by concentrating solely on academic prognoses they may unintentionally suggest to the student that academic success is a satisfactory indicator of other types of success. Regardless

of how gifted or handicapped a student may be academically, he should be encouraged to identify and develop his major strengths to the end that he makes a useful contribution to society through the realization of his unique potentials.

Procedure. Find the student's HSA in one of the columns across the top; then find his ACT Composite in one of the rows down the side. The "derived score" for the student is given in the cell where this row and column intersect. Add the college constant (Table B) to the "derived score" to obtain the predicted GPA at a given college. Refer the result to Table C (expectancy table).

Appendix

Detailed Procedures for Developing Regression Constants

Notation

Composite is the average of the four ACT standard scores.

HSA is the average of the student's most recent term grades in English, mathematics, social studies, and natural science.

Senior year grades are not used. A four-point system is employed (A=4, B=3, C=2, D=1, F=0).

GPA is first year college grade point average. A four-point system is assumed (A=4, B=3, C=2, D=1, F=0).

The X's are standard scores reported for four-year colleges by Astin (1965). X_1 = Intellectualism; X_2 = Estheticism; X_3 = Status; X_4 = Pragmatism; X_5 = Masculinity; X_6 = Selectivity; X_7 = Size; X_8 = Realistic; X_9 = Science; X_{10} = Social; X_{11} = Conventional.

Step 1. Predict the mean ACT Composite score for the college in question by the formula:

$$\begin{aligned} \text{Predicted ACT-C mean} = & -.198380X_1 + .176915X_2 + .151613X_5 \\ & + .241432X_6 + .150621X_9 - 5.115500 \end{aligned}$$

Step 2. Predict the mean HSA for the college in question by the formula:

$$\begin{aligned} \text{Predicted HSA mean} = & .006830X_2 + .009512X_4 - .014413X_5 + .009050X_6 \\ & -.009037X_8 + .003937X_9 + .004894X_{11} + 2.197900 \end{aligned}$$

Step 3. Predict the mean GPA for the college in question by the formula:

$$\begin{aligned} \text{Predicted GPA mean} = & .012854X_2 + .008094X_5 + .011097X_6 - .006939X_7 \\ & + .008122X_9 + .016611X_{10} + .005158X_{11} - .515200 \end{aligned}$$

Step 4. Determine for the college in question the proportion of females among first-time students from Opening fall enrollment in higher education 1965, (U.S. Office of Education, 1966).

Step 5. Compute predicted ACT Composite mean, HSA mean, and GPA mean for each sex by the following equations:

a. Predicted ACT-C mean (males) = Predicted ACT-C mean (Step 1) + .33 times proportion of females.

$$\text{Predicted ACT-C mean (females)} = \text{Predicted ACT-C (males)} - .33.$$

b. Predicted HSA mean (males) = Predicted HSA mean (Step 2) - .33 times proportion of females.

$$\text{Predicted HSA mean (females)} = \text{Predicted HSA mean (males)} + .33.$$

c. Predicted GPA mean (males) = Predicted GPA mean (Step 3) - .29 times proportion of females.

$$\text{Predicted GPA mean (females)} = \text{Predicted GPA mean (males)} + .29.$$

Step 6. Compute regression constants for each sex by the following formulas:

a. Constant (males) = Predicted GPA (males) - .0544 (Predicted ACT-C males) - .4441 (Predicted HSA, males).

b. Constant (females) = Predicted GPA (females) - .0600 (Predicted ACT-C females) - .4748 (Predicted HSA, females).

ACT Research Reports

This report is the twenty-sixth in a series published by the Research and Development Division of the American College Testing Program. The research reports have been deposited with the American Documentation Institute, ADI Auxiliary Publications Project, Photoduplication Service, Library of Congress, Washington, D. C. 20540. (ADI Document numbers and prices are given below.) Photocopies and 35 mm. microfilms are available at cost from ADI; order by ADI Document number. Advance payment is required. Make checks or money orders payable to: Chief, Photoduplication Service, Library of Congress. Printed copies are available from the Research and Development Division, American College Testing Program.

Reports preceded by an asterisk (*) in the list below are available only from ADI.

- *No. 1 A Description of American College Freshmen, by C. Abe, J. L. Holland, S.W. Lutz, & J. M. Richards, Jr., (ADI Doc. 8554; photo, \$8.75; microfilm, \$3.00)
- *No. 2 Academic and Nonacademic Accomplishment: Correlated or Uncorrelated? by J. L. Holland, & J. M. Richards, Jr., (ADI Doc. 8555; photo, \$3.75; microfilm, \$2.00)
- *No. 3 A Description of College Freshmen: I. Students with Different Choices of Major Field, by C. Abe, & J. L. Holland (ADI Doc. 8556; photo, \$7.50; microfilm, \$2.75)
- *No. 4 A Description of College Freshmen: II. Students with Different Vocational Choices, by C. Abe, & J. L. Holland (ADI Doc. 8557; photo, \$7.50; microfilm, \$2.75)
- *No. 5 A Description of Junior Colleges, by J. M. Richards, Jr., L.M. Rand, & L. P. Rand (ADI Doc. 8558; photo, \$3.75; microfilm, \$2.00)
- *No. 6 Comparative Predictive Validities of the American College Tests and Two Other Scholastic Aptitude Tests, by L. Munday (ADI Doc. 8559; photo, \$2.50; microfilm \$1.75)
- No. 7 The Relationship Between College Grades and Adult Achievement: A Review of the Literature, by D.P. Hoyt (ADI Doc. 8632; photo, \$7.50; microfilm, \$2.75)
- No. 8 A Factor Analysis of Student "Explanations" of Their Choice of a College, by J. M. Richards, Jr. & J. L. Holland (ADI Doc. 8633; photo, \$3.75; microfilm, \$2.00)

ACT Research Reports (con't.)

- No. 9 Regional Differences in Junior Colleges, by J. M. Richards, Jr., L. P. Rand, & L. M. Rand
(ADI Doc. 8743; photo, \$2.50; microfilm, \$1.75)
- No. 10 Academic Description and Prediction in Junior Colleges, by D. P. Hoyt, & L. Munday
(ADI Doc. 8856; photo, \$3.75; microfilm, \$2.00)
- No. 11 The Assessment of Student Accomplishment in College, by J. M. Richards, Jr., J. L. Holland, & S. W. Lutz
(ADI Doc. 8955; photo, \$3.75; microfilm, \$2.00)
- No. 12 Academic and Nonacademic Accomplishment in a Representative Sample taken from a Population of 612,000, by J. L. Holland, & J. M. Richards, Jr.
(ADI Doc. 8992; photo, \$3.75; microfilm, \$2.00)
- No. 13 The Prediction of Student Accomplishment in College, by J. M. Richards, Jr., J. L. Holland, & S. W. Lutz
(ADI Doc. 9020; photo, \$5.00; microfilm, \$2.25)
- No. 14 Changes in Self-Ratings and Life Goals Among Students at Colleges with Different Characteristics, by R. W. Skager, J. L. Holland, & L. A. Braskamp
(ADI Doc. 9069; photo, \$3.75; microfilm, \$2.00)
- No. 15 Can Computers Write College Admissions Tests? by J. M. Richards, Jr.
(ADI Doc. 9174; photo, \$2.50; microfilm, \$1.75)
- No. 16 Changes in Self-Ratings and Life Goals as Related to Student Accomplishment in College, by R. W. Skager, & L. A. Braskamp
(ADI Doc. 9214; photo, \$2.50; microfilm, \$1.75)
- No. 17 Family Income and the Characteristics of College-Bound Students, by L. L. Baird
(ADI Doc. 9378; photo, \$3.75; microfilm, \$2.00)
- No. 18 Predicting a Student's Vocational Choice, by J. L. Holland, & S. W. Lutz
(ADI Doc. 9433; photo, \$2.50; microfilm, \$1.75)
- No. 19 The Educational Goals of College-Bound Youth, by L. L. Baird
(ADI Doc. 9472; photo, \$5.00; microfilm, \$2.25)
- No. 20 Who Goes Where to Junior College? by J. M. Richards, Jr. & L. A. Braskamp
(ADI Doc. 9571; photo, \$3.75; microfilm, \$2.00)

ACT Research Reports (cont'd.)

- No. 21 Predicting Student Accomplishment in College from the ACT Assessment, by J. M. Richards, Jr., & S. W. Lutz
(ADI Doc. 9594; photo, \$6.25; microfilm, \$2.50)
